Single Particle Inclusive & Jet Inclusive Production

Particles: h

Jets: X

LO Dimension

$$E \frac{d^3\sigma}{dp^3} \sim \frac{d^2\sigma}{dp_T^2 dy} \sim \frac{d\hat{\sigma}_{ab}(\alpha_s(\mu_R^2), s/\mu_R^2, s/\mu_F^2)}{d\hat{t}}$$

$$\sim \frac{\text{cm}^2}{\text{GeV}^2} \sim \frac{1}{\text{GeV}^4} \quad 2 \rightarrow 2 \text{ scattering}$$

$$\sim 1/\text{GeV}^6 \text{ for } 2 \rightarrow 3 \text{ scattering}$$

Particles: h

$$E d\sigma/d^3p(s, t, u; A+B \rightarrow h+X) = \int_{x_a^{\min}}^1 dx_a \int_{x_b^{\min}}^1 dx_b G_{A \to a}(x_a) G_{B \to b}(x_b) D_c^h(z_c) \frac{1}{z_c} \frac{1}{\pi} \frac{d\hat{\sigma}}{d\hat{t}}(\hat{s}, \hat{t}; q_a+q_b \rightarrow q'_a+q'_b)$$

F, F & F

Jets: X

$$E \frac{d^3\sigma}{dp^3} = \sum_{a,b} \int dx_1 dx_2 f_a(x_1, \mu_F^2) f_b(x_2, \mu_F^2) \frac{d\hat{\sigma}_{ab}(\alpha_s(\mu_R^2), s/\mu_R^2, s/\mu_F^2)}{d\hat{t}} \otimes \text{Frag} \otimes \text{Had}$$

QCD Factorization Theorem

P_T & “Other” Variable: Rapidity & Radial x_R

x_R is a “final state” scaling variable that **controls kinematic boundary suppression** that is not respected by $x_{||}$ and x_T .

Rapidity and pseudo rapidity:

$$y = \frac{1}{2} \ln \left(\frac{E + p_z}{E - p_z} \right) \approx \eta = -\ln \left(\tan \left(\frac{\theta}{2} \right) \right)$$

Radial scaling x_R :

$$x_R = \frac{E}{E_{\max}} = \frac{2\sqrt{(p_T^2 \cosh^2(y)(1 + (m_J^2/p_T^2) \tanh^2(y)) + m_J^2)}}{\sqrt{s - m_{QN}^2}}$$

$$\approx \frac{2p_T \cosh(y)}{\sqrt{s}} \sqrt{\left(1 + \frac{m_J^2}{p_T^2} \tanh^2(y) \right)}$$

$$\approx \frac{2p_T \cosh(\eta)}{\sqrt{s}}$$

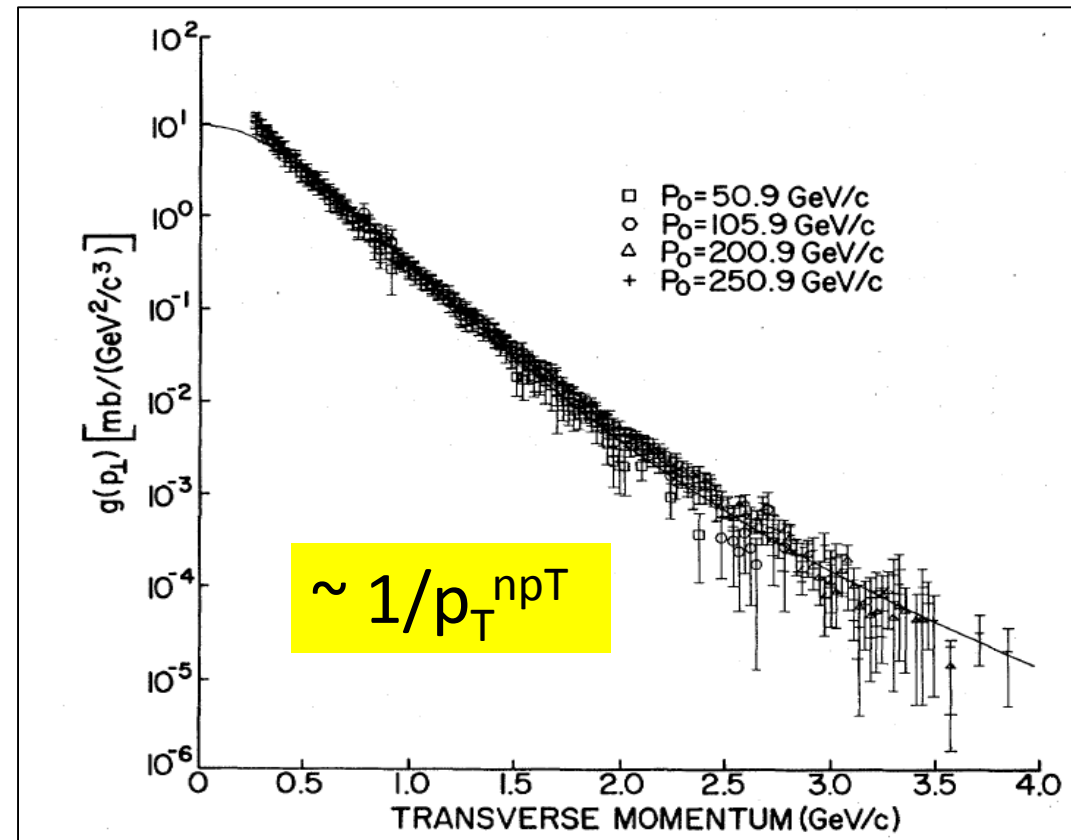

m_{QN} =mass to satisfy QN conservation

E and E_{\max} are energy of jet (particle) and maximum energy, respectively in the COM. m_j is mass of jet (particle).

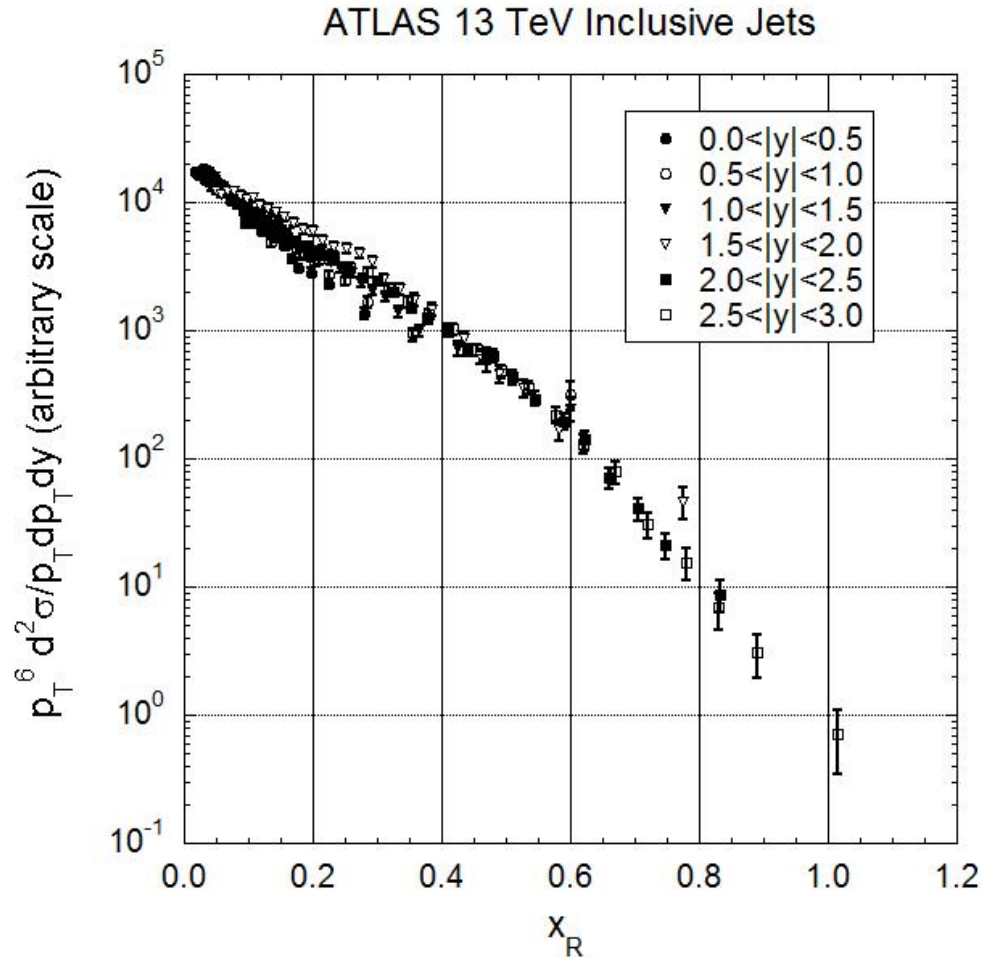

Radial Scaling in Inclusive p-p π^0 Production

$$E \frac{d^3\sigma}{dp^3} = F(s, p_T, x_R) \approx F(p_T, x_R) \sim A(p_T) f(x_R)$$

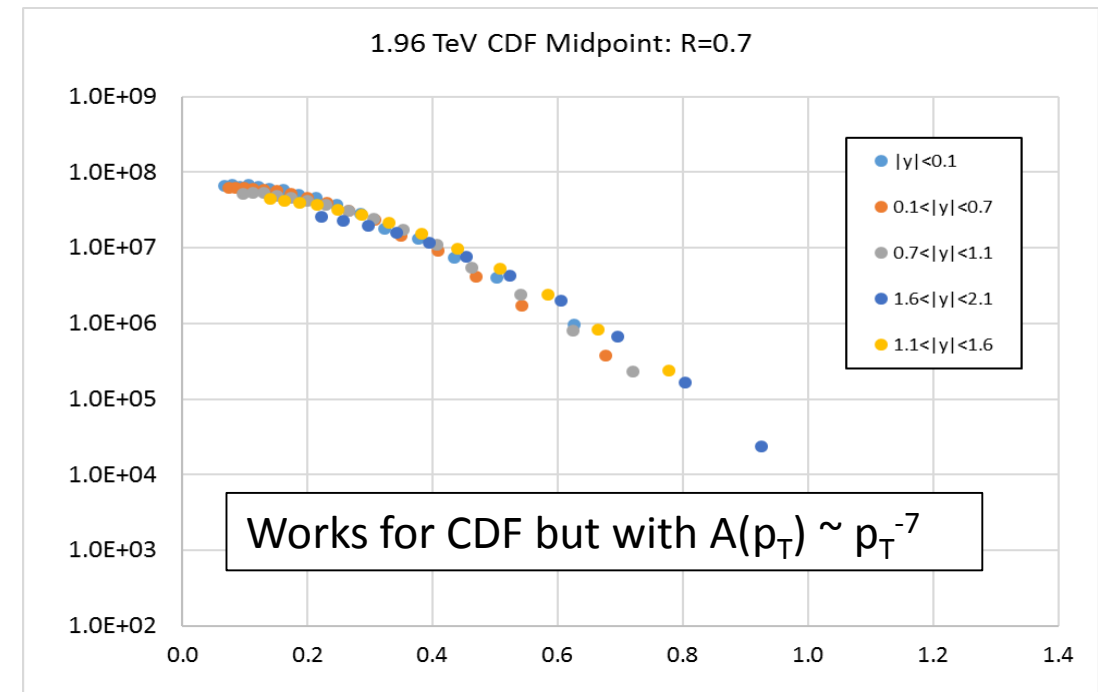

D. C. Carey, ... FET Phys. Rev. Lett. 33,
No. 5, 327 (29 July 1974)

$$A(p_T) \sim p_T^{-6}$$

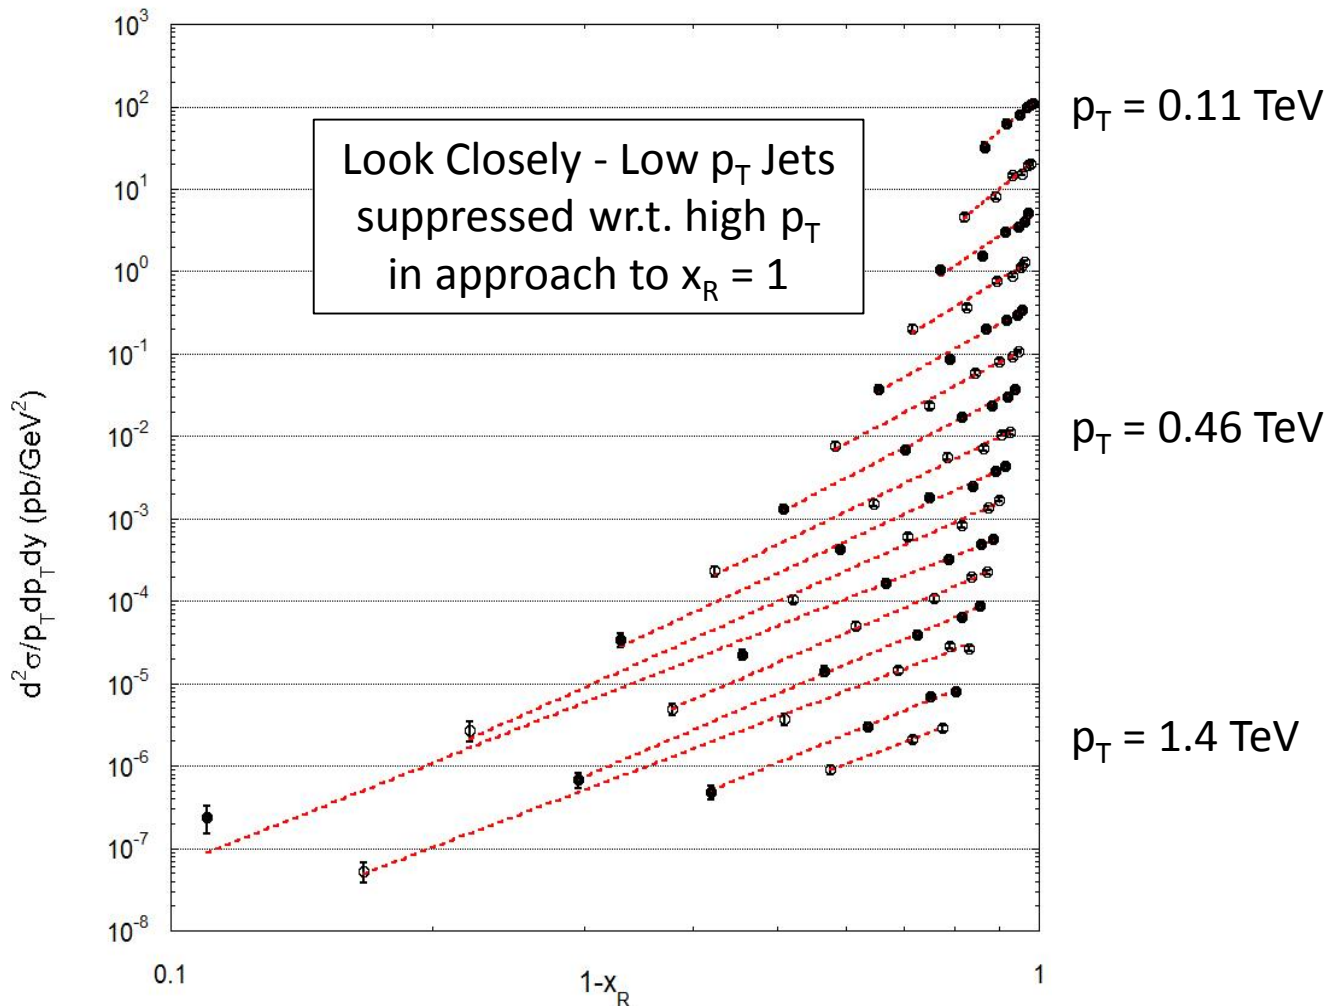

Find an approximate Radial Scaling for Inclusive Jet Production – similar to that observed in single particle inclusive production.

13 TeV ATLAS Jets – constant p_T vs. $(1-x_R)$

ATLAS Inclusive Jets 13 TeV R=0.4

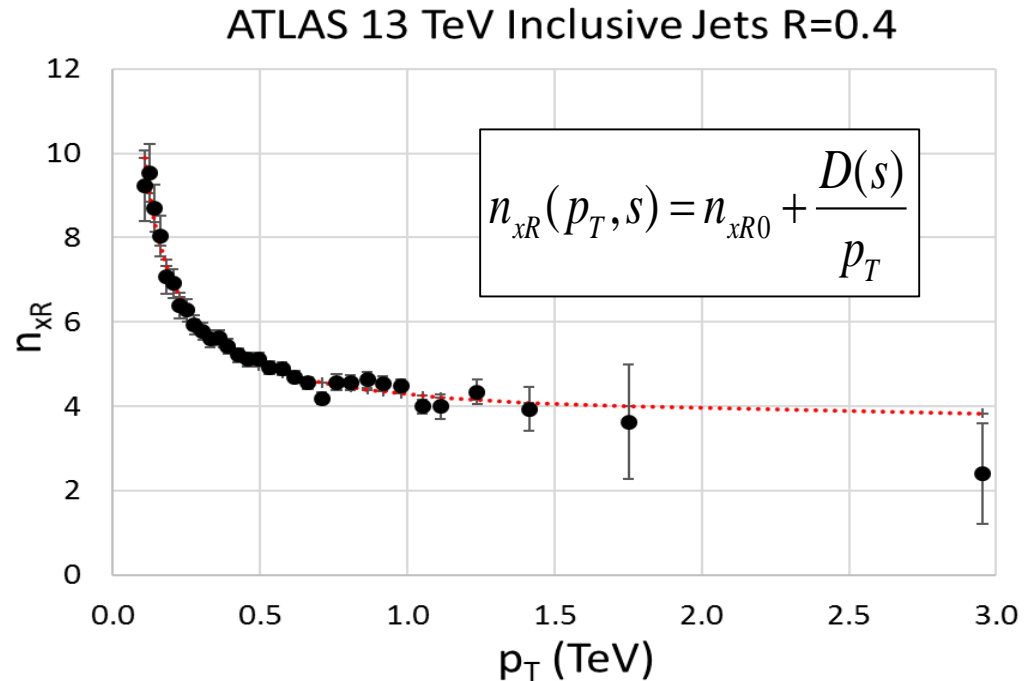

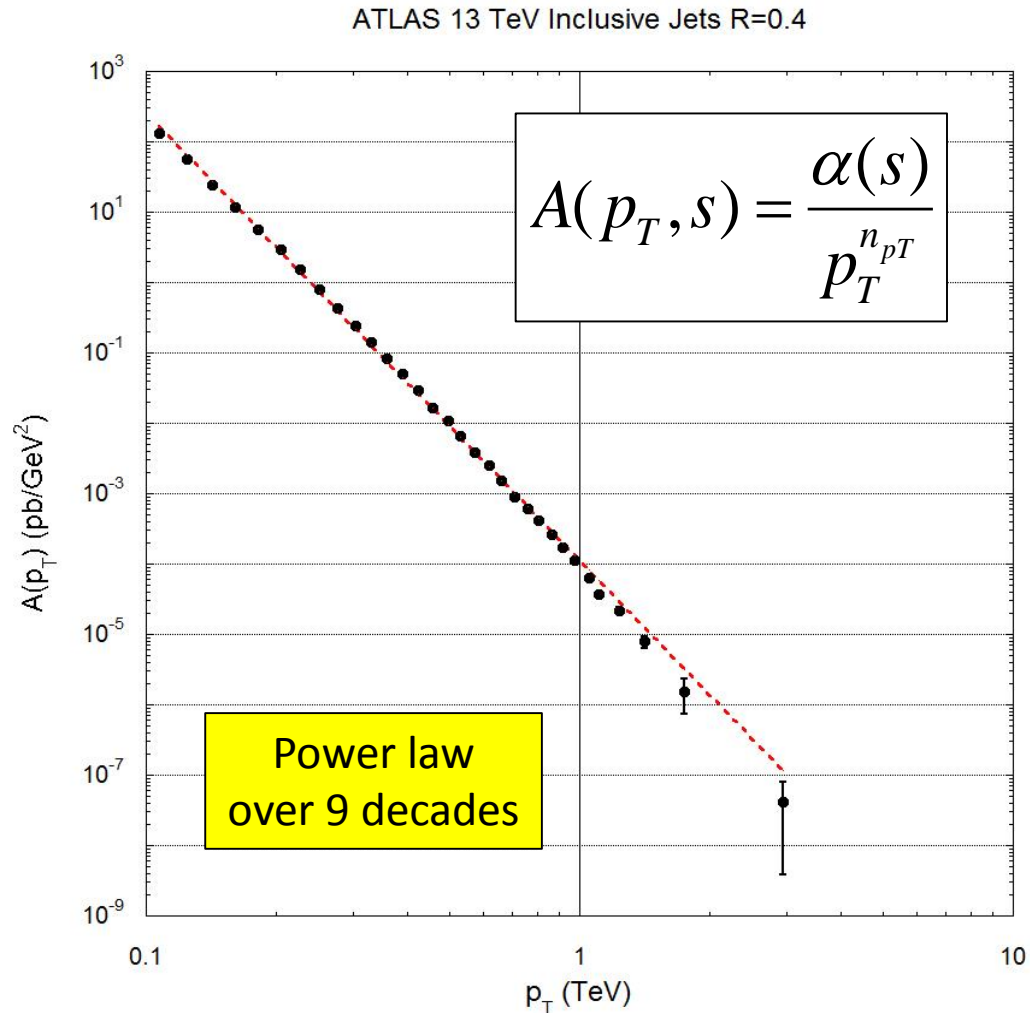

A more refined analysis is to determine $A(p_T)$ by power-law fits in $(1-x_R)$ for constant p_T :

$$\frac{d^2\sigma}{p_T dp_T d\eta} \sim A(p_T) (1-x_R)^{n_{xR}}$$

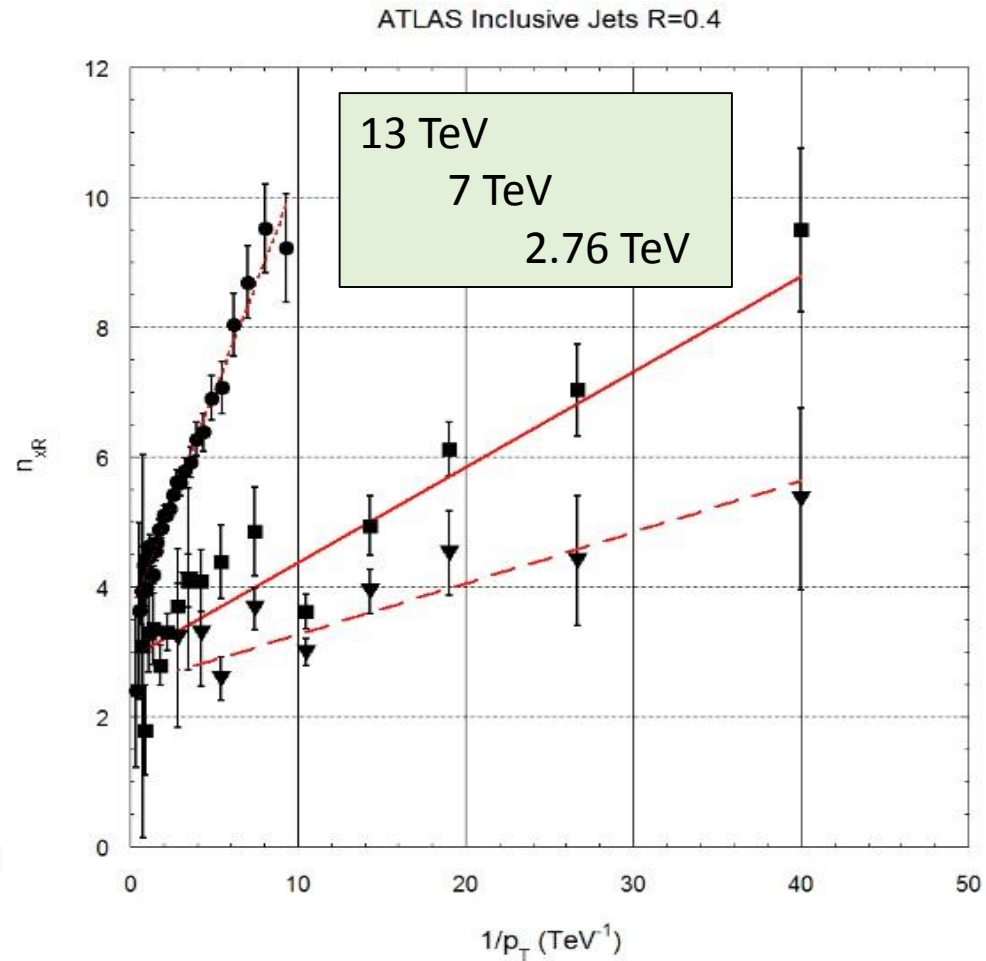

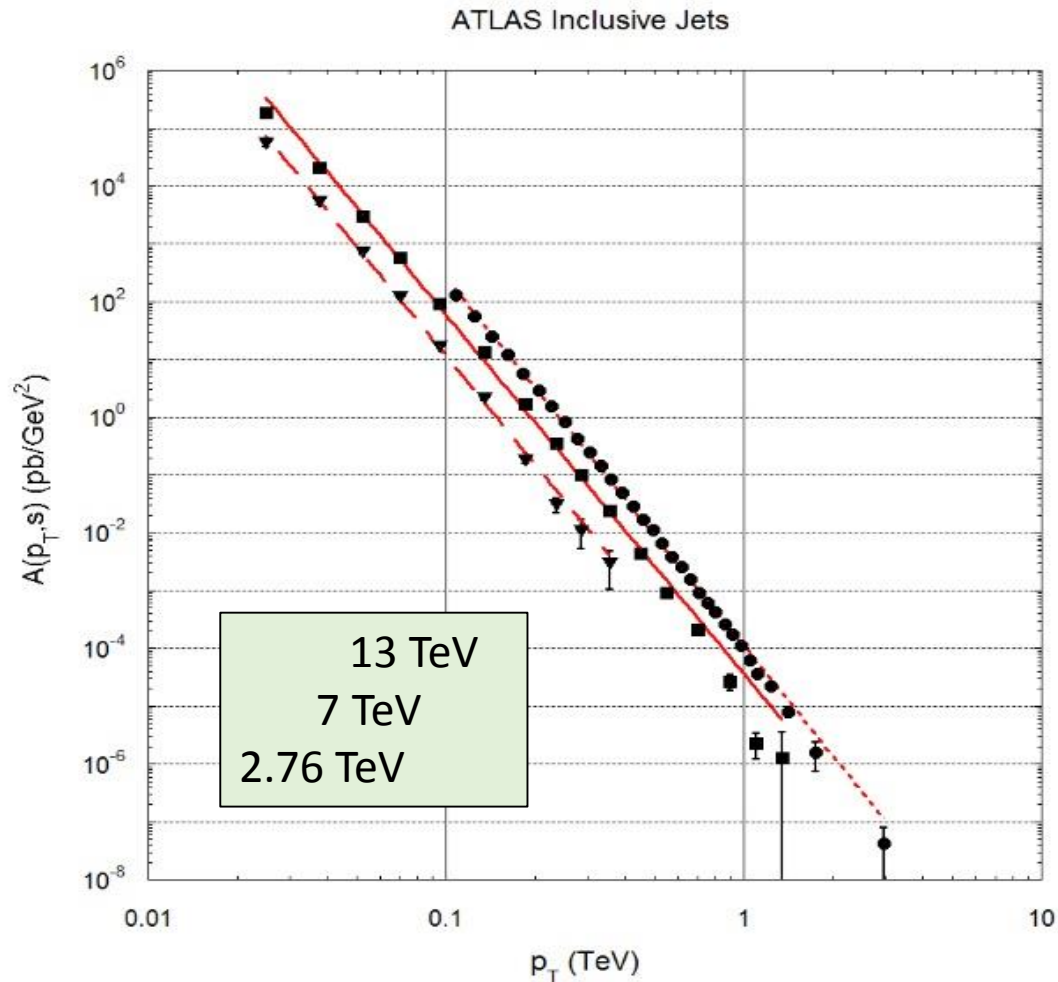

Now study the behavior of $A(p_T)$ and n_{xR} as function of p_T , \sqrt{s} and process.

Fit Parameters 13 TeV ATLAS Inclusive Jets

$\alpha(s) = (1.13 \pm 0.02) \times 10^{-4} \text{ (pb/GeV}^2\text{) TeV}^{n_{pT}}$
 $n_{pT} = 6.36 \pm 0.01$
 $D(s) = 0.68 \pm 0.03 \text{ (TeV}^{-1}\text{)}$
 $n_{xR0} = 3.61 \pm 0.07$

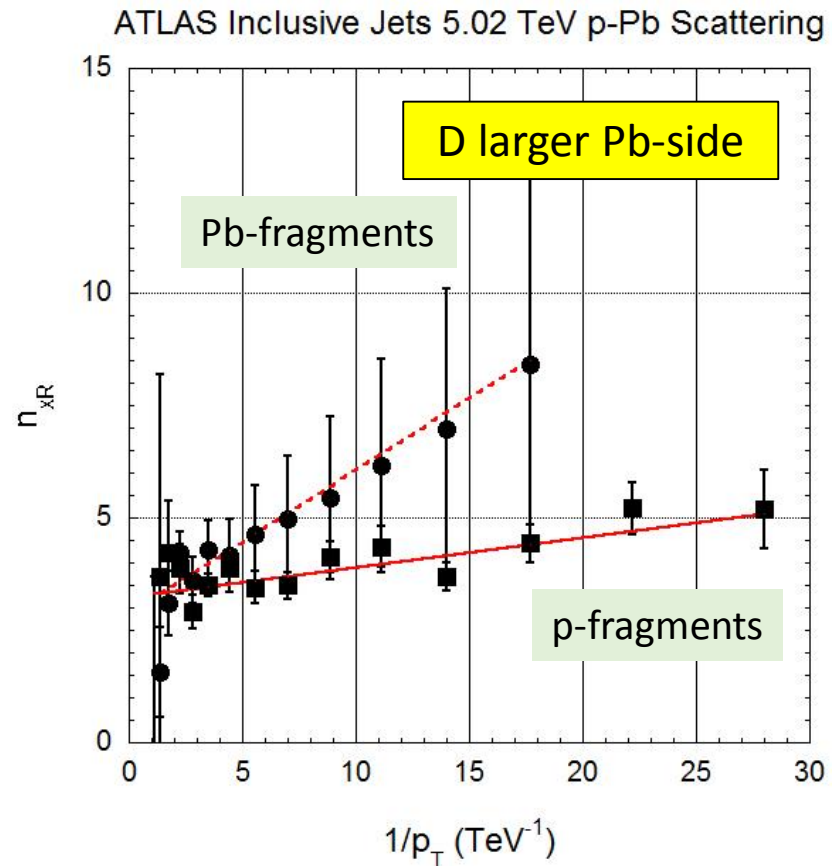

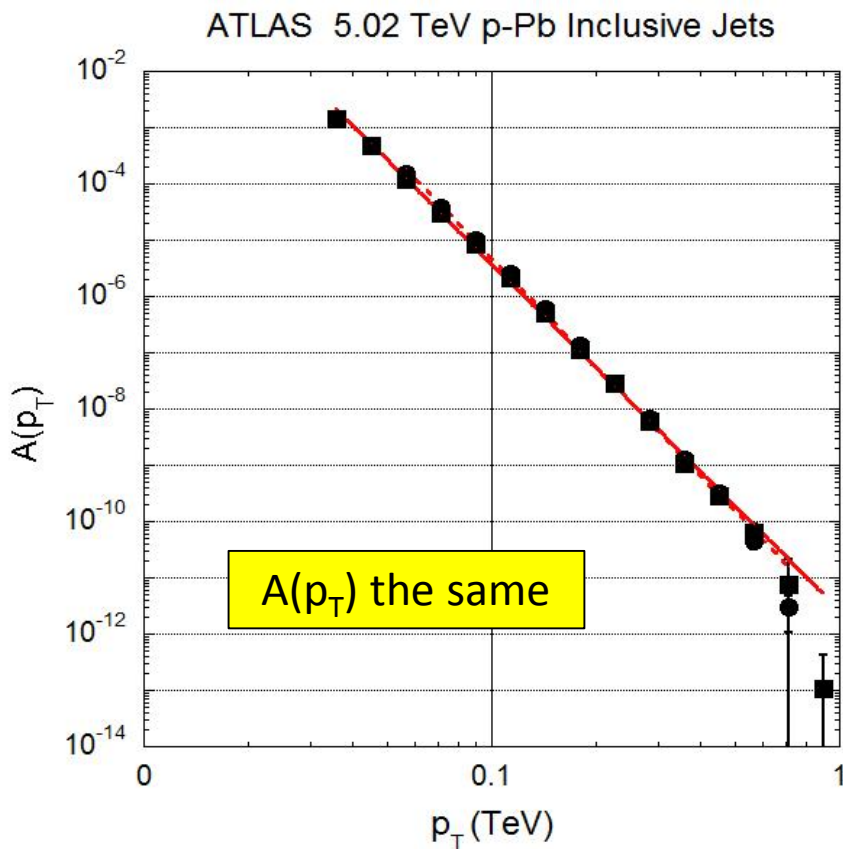

ATLAS Jets at Other p-p \sqrt{s} Energies

$\alpha(s)$ grows with s
 $n_{pT} \approx \text{constant}$
 $D(s)$ grows with s
 $n_{xR0} \approx \text{constant}$

ATLAS p-Pb Jets $\sqrt{s_{nn}} = 5.02$ TeV

- Compare p-fragmentation side with Pb-fragmentation side (0%-90%)

	n_{pT}	D	n_{xR0}

$$\frac{d^2\sigma}{p_T dp_T dy}(s, p_T, y; \alpha, n_{pT}, D, n_{xR0}) = \frac{\alpha(s)}{p_T^{n_{pT}}} (1 - x_R)^{\frac{D(s)}{p_T} + n_{xR0}}$$

$$x_R = \frac{E}{E_{\max}} = \frac{2\sqrt{(p_T^2 \cosh^2(y)(1 + (m_J^2/p_T^2) \tanh^2(y)) + m_J^2)}}{\sqrt{s}}$$

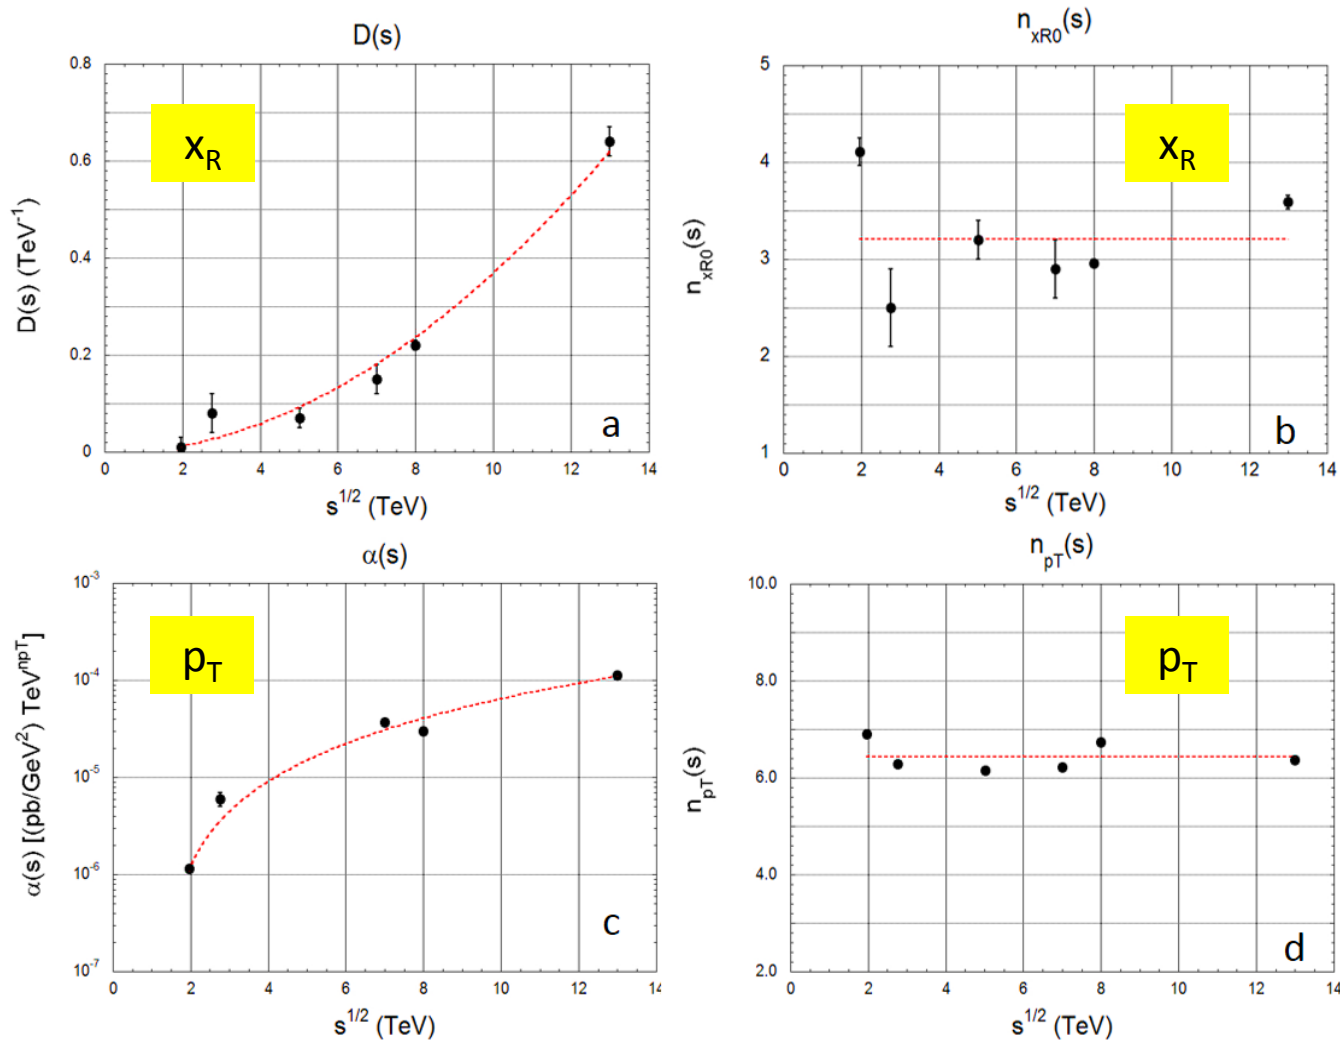

$$\approx \frac{2p_T \cosh(y)}{\sqrt{s}} \sqrt{\left(1 + \frac{m_J^2}{p_T^2} \tanh^2(y)\right)}$$

where: $m_J/p_T < R/\sqrt{2} = 0.28$ for

$$R = \sqrt{(\Delta\phi^2 + \Delta\eta^2)}$$

(D. W. Kolodrubetz, et al., "Factorization for Jet Radius Logarithms in Jet Mass Spectra at the LHC", arXiv:1605.08038v1)

Inclusive Jet Fit Parameters in p_T and x_R

Conclusions:

p_T - behavior

$n_{pT} \approx \text{constant} = 6.5 \pm 0.3$

$\alpha(s)$ grows linearly with s

Quality of power-law fits in p_T is low.

Better fit:

$$A(p_T, s) = \exp\left(\beta(s)(\ln(p_T))^2\right) \frac{\alpha(s)}{p_T^{n_{pT}}}$$

$(1-x_R)$ behavior

$n_{xR0} \approx \text{constant} = 3.3 \pm 0.5$

$D(s)$ grows linearly with s

Same \sqrt{s} data combined:

$(D0 \otimes CDF, ATLAS \otimes CMS)$

Single Particle Inclusive Reactions

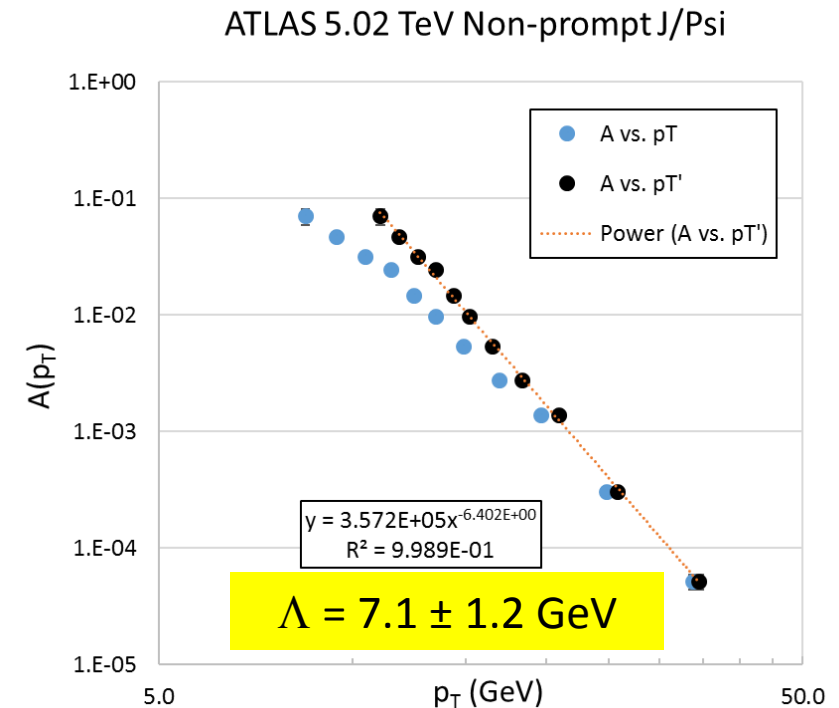

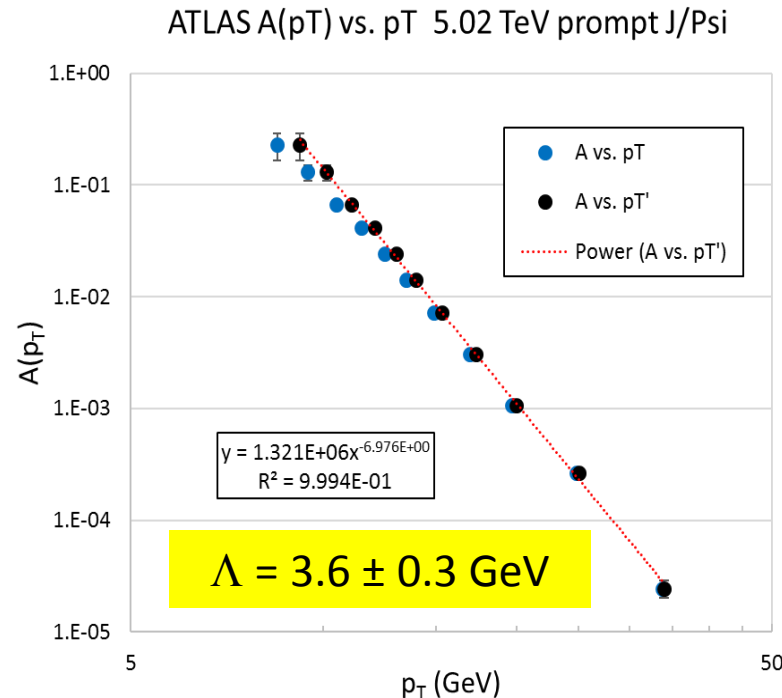

$$\frac{d^2\sigma}{p_T dp_T dy}(s, p_T, y; \alpha, \Lambda, n_{pT}, m, D, n_{xR0})$$

$$= \frac{\alpha(s)}{(\Lambda^2 + p_T^2)^{\frac{n_{pT}}{2}}} \left(1 - \frac{2\sqrt{(p_T^2 \cosh^2(y)(1 + (m^2/p_T^2) \tanh^2(y)) + m^2)}}{\sqrt{s}} \right)^{\frac{D(s)}{p_T} + n_{xR0}}$$

$$= \frac{\alpha(s)}{(\Lambda^2 + p_T^2)^{\frac{n_{pT}}{2}}} (1 - x_R)^{\frac{D(s)}{p_T} + n_{xR0}}$$

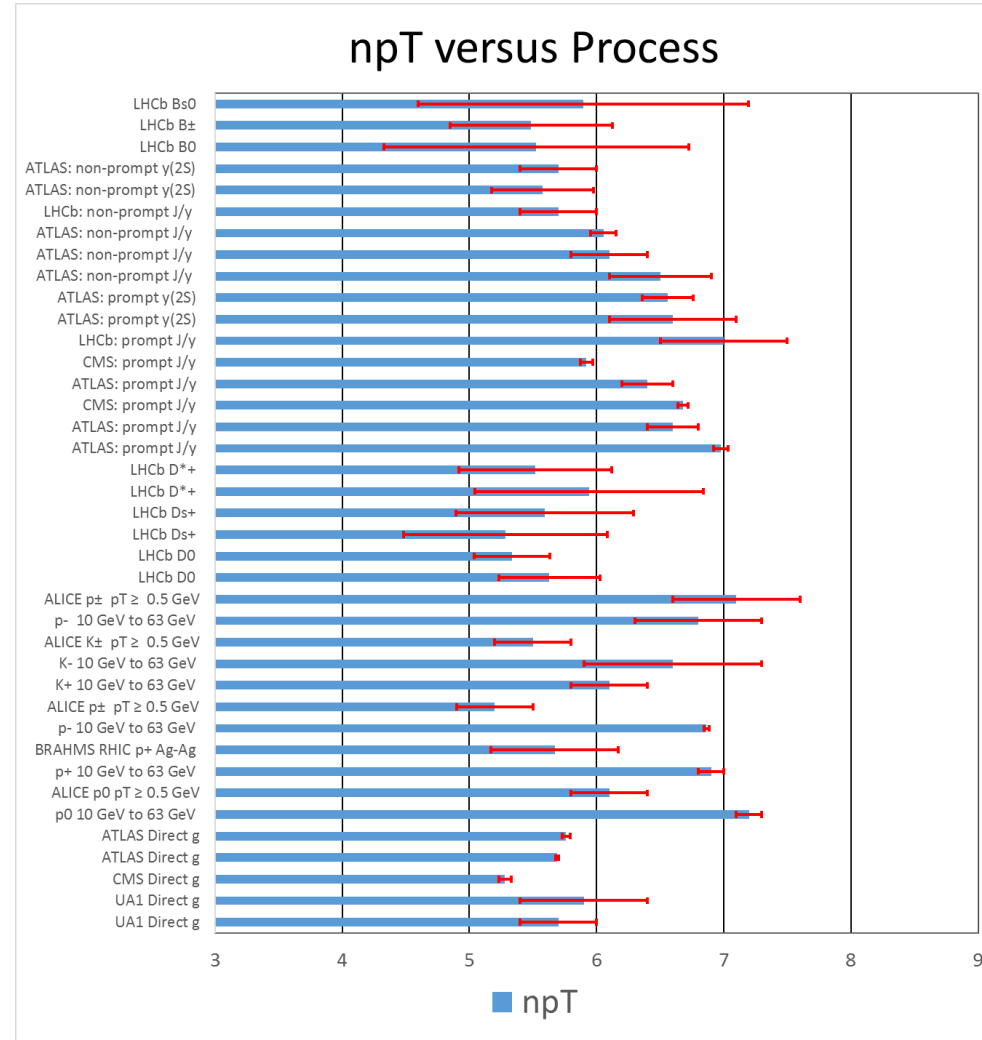

$$p_T' = \sqrt{(\Lambda^2 + p_T^2)}$$

Parameterization of cross section at low p_T needs another term Λ (transverse mass \otimes intrinsic k_T)

A(p_T): Single Particle Inclusive 0.063 TeV ≤ √s ≤ 13 TeV

Λ Parameter

Prompt Single Particle Inclusive Λ vs. M

Λ Prompt vs. Non-prompt

Λ parameter for prompt single particle inclusive is linear with mass of particle:
 $\Lambda = 1.1 M + 0.4$ (GeV)
 Λ for non-prompt tends to be larger than Λ prompt (J/ ψ) but better data needed $\psi(2S)$.

QCD through the Prism of Radial Scaling

- The p_T -dependence of the invariant inclusive cross sections seems to be independent of process and energy over a wide range as a power law: $1/p_T^{(6.2 \pm 0.6)}$ in the limit $x_R \rightarrow 0$. “Higher Twists” have been known to dominate for a long time but this analysis demonstrates this widely. **All are consistent with the dimension of 2 \rightarrow 3 scattering.**
- The x_R dependence is consistent with a power law $(1-x_R)^{n_{xR}}$, where n_{xR} is qualitatively dependent on the number of spectator quarks.
- At **high \sqrt{s}** and **HI** collisions $n_{xR} = D/p_T + n_{xR0} \rightarrow$ **Jets at low p_T strongly suppressed.**
- Determining Λ gives a hint of **production mechanism** \sim linear with mass direct, larger for indirect production.
- The data are well-represented by pQCD calculations to NLO (PHYTHIA, SHERPA, JetPhox, PeTer). Experiment authors show agreement with simulations but generally do not try to factorize the p_T -dependence from the y or x_R dependence. Doing so would show commonalities and highlight differences. **What about 100 TeV?**

Preliminary version of this work:

Backup

Inclusive Jets & Inclusive Single Particles

$$\frac{d^2\sigma}{p_T dp_T dy}(s, p_T, y; \alpha, \Lambda, n_{pT}, m, D, n_{xR0})$$

$$= \frac{\alpha(s)}{(\Lambda^2 + p_T^2)^{\frac{n_{pT}}{2}}} \left(1 - \frac{2\sqrt{(p_T^2 \cosh^2(y)(1 + (m^2/p_T^2) \tanh^2(y)) + m^2)}}{\sqrt{s}} \right)^{\frac{D(s)}{p_T} + n_{xR0}}$$

$$= \frac{\alpha(s)}{(\Lambda^2 + p_T^2)^{\frac{n_{pT}}{2}}} (1 - x_R)^{\frac{D(s)}{p_T} + n_{xR0}}$$

$n_{pT} \approx 6$ independent of process in $x_R \rightarrow 0$ limit.
 Λ depends linearly on mass of particle.
 $\alpha(s)$ and $D(s)$ are roughly linear in s for jets.
 $n_{xR0} \approx \text{constant}$ for inclusive jets

Preliminary version of this work:
 F. E. Taylor, "Radial Scaling in Inclusive Jet Production at Hadron Colliders",
<https://arxiv.org/abs/1704.07341>, [v1] Mon, 24 Apr 2017

The Paradigm for Inclusive Jet Production

Jets are produced by hard parton scattering ($qq \rightarrow qq$, $gg \rightarrow gg$, $gq \rightarrow gq$). The scattered parton hadronizes into a jet of particles.

QCD Factorization Theorem

$$E \frac{d^3\sigma}{dp^3} = \sum_{a,b} \int dx_1 dx_2 f_a(x_1, \mu_F^2) f_b(x_2, \mu_F^2) \frac{d\hat{\sigma}_{ab}(\alpha_s(\mu_R^2), s/\mu_R^2, s/\mu_F^2)}{d\hat{t}} \otimes Frag \otimes Had$$

These *10s of parameters and factors* are put together in simulations of inclusive jet production at the LHC.

Dimensions:

$$E \frac{d^3\sigma}{dp^3} \sim \frac{d^2\sigma}{dp_T^2 dy} \sim \frac{d\hat{\sigma}_{ab}(\alpha_s(\mu_R^2), s/\mu_R^2, s/\mu_F^2)}{d\hat{t}}$$

$$\sim \frac{cm^2}{GeV^2} \sim \frac{1}{GeV^4}$$

Would expect invariant cross section to show $1/p_T^4$ behavior if LO scattering dominates

ATLAS Inclusive Jet Production at 13 TeV

- Jets defined by anti- k_t algorithm with $R=(\Delta\phi^2+\Delta y^2)^{1/2} = 0.4$
- Pythia 8.186 with A14 tune, NLOjet++. Involves integrations & summations using Monte Carlo methods
- Data compared to NLO pQCD calculation **2 -> 2 + NLO processes**, leading logarithmic p_T -ordered parton shower, hadronization with the Lund string model.

ATLAS NOTE
ATLAS-CONF-2016-092
21st August 2016

Line Counting, Higher Twists, Diquarks

- Dimensional Analysis $M \sim [\text{cm}]^{n_A - 4}$ $\frac{d^2\sigma}{p_T dp_T dy} \sim \frac{|M|^2}{\hat{s}^2}$ $\frac{d^2\sigma}{p_T dp_T dy} \sim \frac{1}{p_T^{2n_A - 4}}$

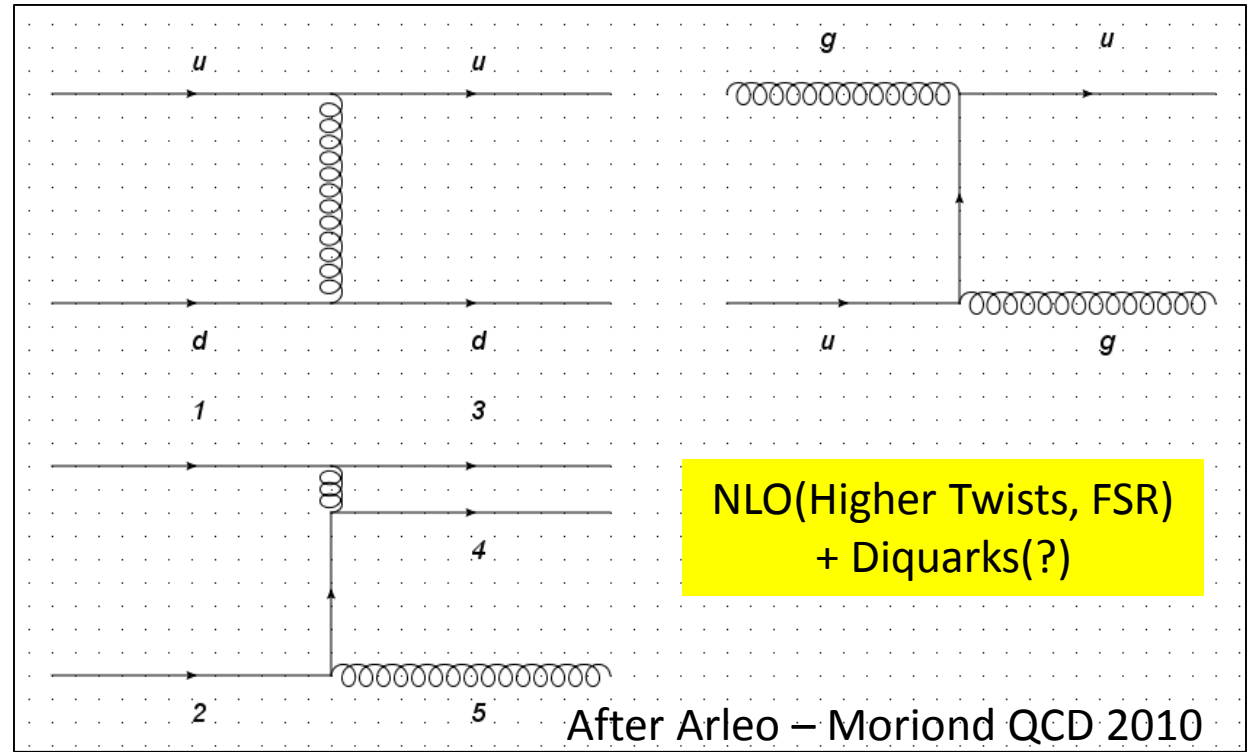

n_A = number of active fields

$$\frac{d^2\sigma}{p_T dp_T dy} \sim \frac{1}{p_T^4}$$

$n_A = 4$ 2 \rightarrow 2 scattering
HIDDEN $x_R \rightarrow 0$

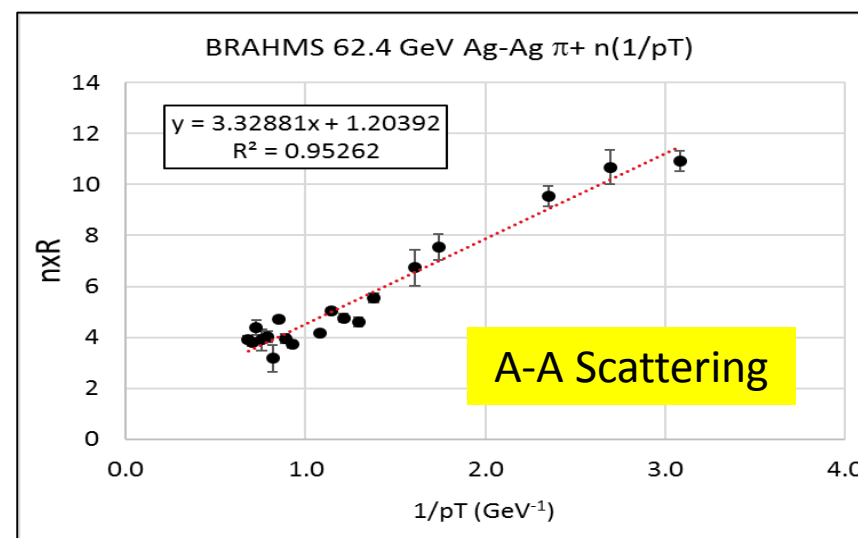

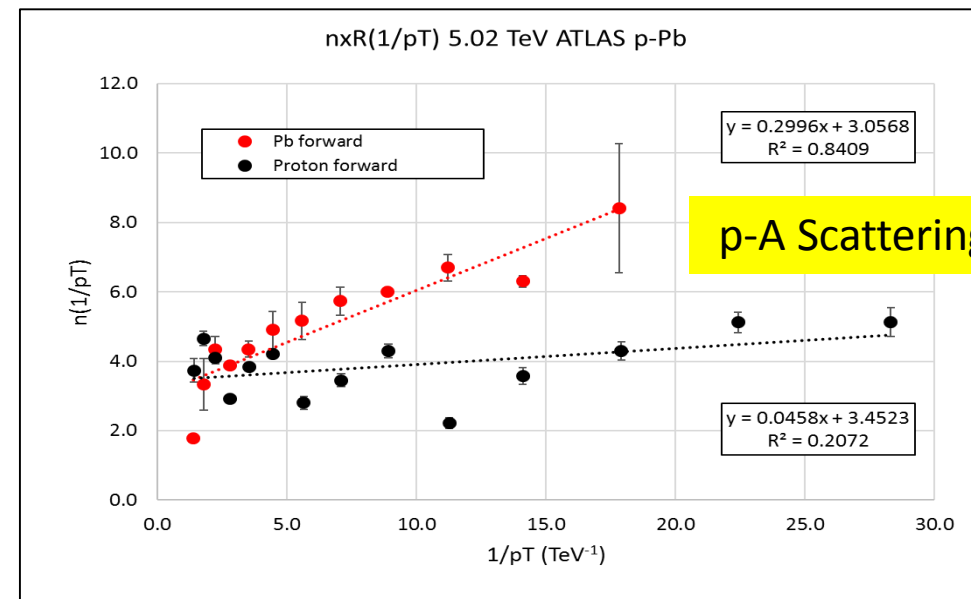

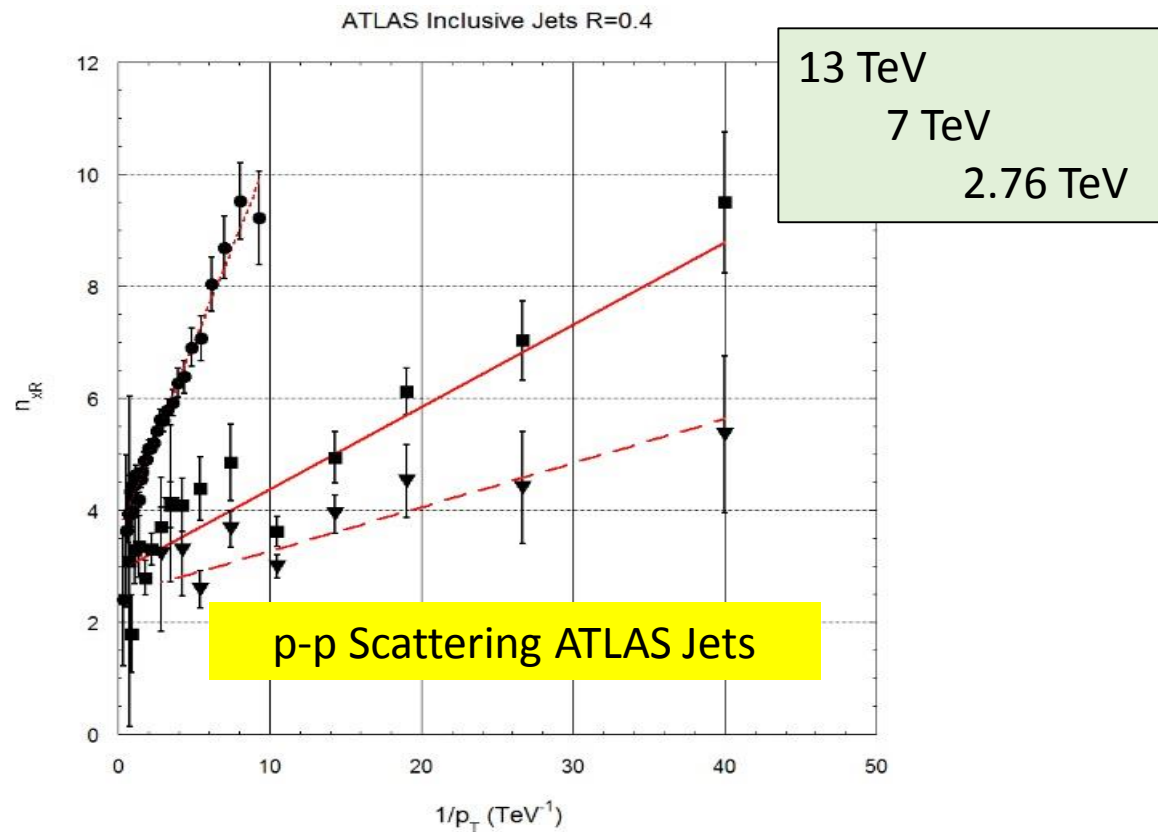

$$\frac{d^2\sigma}{p_T dp_T dy} \sim \frac{1}{p_T^6}$$

$n_A = 5$ 2 \rightarrow 3 scattering
DOMINATES $x_R \rightarrow 0$

X_R

Jets in p-p, p-A, A-A have similar behavior

All behave: $(1 - x_R)^{(D/p_T + n_{0xR})}$

13 TeV ATLAS Jets Plotted as a function of x_R

13 TeV R=0.4 ATLAS

If there is a hard $2 \rightarrow 2$ scattering core by naive dimensional analysis then:

$$\frac{d\sigma(ab \rightarrow x)}{dQ^2} \sim \frac{1}{Q^4} \rightarrow \frac{d^2\sigma(pp \rightarrow Jets)}{p_T dp_T dy} \sim \frac{1}{p_T^4}$$

Thus would expect:

$$p_T^4 \left(\frac{d^2\sigma(pp \rightarrow Jets)}{p_T dp_T dy} \sim \frac{1}{p_T^4} \right) \sim F(x_R)$$

Note: Have approximated η by y

Physical Picture: Inclusive Jets & Pions

Low p_T

Choose 4 points in phase space: $(p_{T,L,H}, x_{R1}, x_{R2})$

High p_T

$$R(p_T; \{x_{R1}, x_{R2}\}) = \frac{\sigma_1}{\sigma_2} = \frac{(1-x_{R1})^{\left(\frac{D(p_T)}{p_T} + n_{xR0}\right)}}{(1-x_{R2})^{\left(\frac{D(p_T)}{p_T} + n_{xR0}\right)}}$$

“Beam fragmentation region”

“Beam fragmentation region” augmented by increasing \sqrt{s} and/or by increasing beam A in Heavy Ion Collisions.

Jet quenching in both cases. Same Physics?

$$R(p_{TLow}; \{x_{R1}, x_{R2}\}) < R(p_{THigh}; \{x_{R1}, x_{R2}\})$$

Jet strongly attenuated on approach to kinematic boundary because of large “D” term

Jet less strongly attenuated on approach to kinematic boundary because “D” term $\rightarrow 0$

η verses x_R

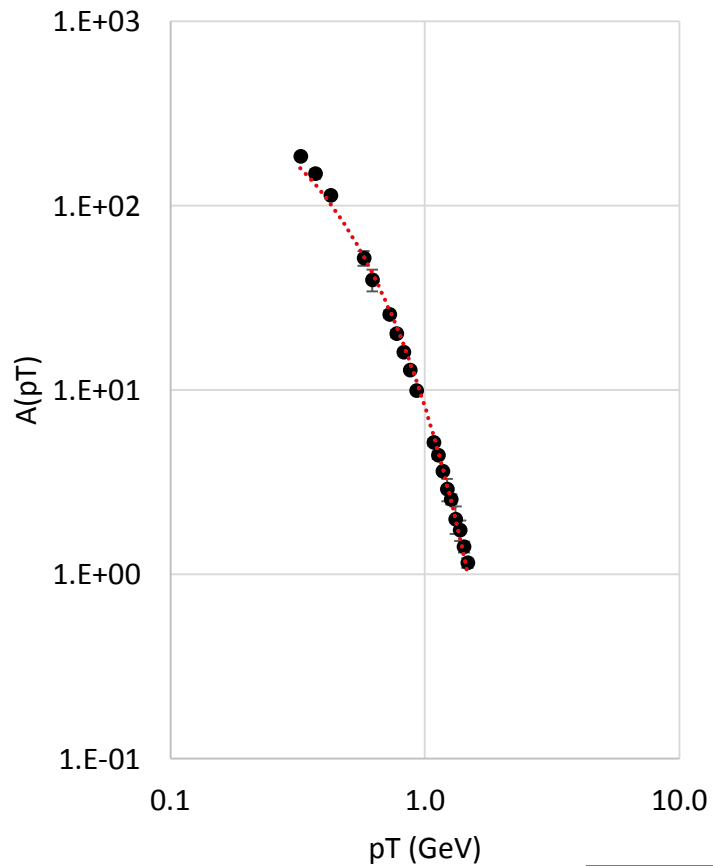

$$\eta(x_R, s, p_T) = \ln \left(\frac{x_R \sqrt{s}}{2p_T} + \sqrt{\frac{x_R s}{4p_T^2} - 1} \right)$$

$$\eta_{\max} = \ln \left(\frac{\sqrt{s}}{2p_T} + \sqrt{\frac{s}{4p_T^2} - 1} \right)$$

Analyses in constant η couples p_T and x_R so that the hard scattering part of $d^2\sigma/p_T dp_T d\eta$ that is characterized by p_T is entangled with a change in x_R – the kinematic boundary parameter.

BRAHMS π^+ from Ag-Ag Collisions 62.4 GeV

$A(p_T)$ vs. p_T

$$A(p_T) = \alpha_0 \frac{\Lambda^{n_{pT}-4}}{(\Lambda^2 + p_T^2)^{\frac{n_{pT}}{2}}}$$

$A(p_T')$ vs. $p_T' = (\Lambda^2 + p_T^2)^{1/2}$

$nxR(1/p_T)$ vs. $1/p_T$

13 TeV ATLAS Inclusive Jets - Using $A(p_T) \sim p_T^{-4}$

13 TeV R=0.4 ATLAS Inclusive Jets

Naively, does not indicate hard $2 \rightarrow 2$ scatterings – such as:

$$qq \rightarrow qq$$

$$gg \rightarrow gg$$

$$gq \rightarrow gq$$

are dominating.

Note: plotted errors are statistical and systematic errors added in quadrature.

Residuals of Quadratic ln(p_T) Fit - 13 TeV ATLAS

$d\sigma/d\eta$ in Toy Model

$$\frac{d\sigma}{d\eta} = \int_{p_{T\min}}^{p_{T\max}} \frac{d^2\sigma}{p_T dp_T d\eta} p_T dp_T = \int_{p_{T\min}}^{p_{T\max}} \frac{a}{p_T^{n_{pT}}} \left(1 - \frac{2p_T}{\sqrt{s}} \cosh(\eta) \right)^{n_{xR}} p_T dp_T$$

$$\frac{d\sigma(p_{T\min}, p_{T\max})}{d\eta} = aF \left(p_{T\min}, p_{T\max}, \frac{\cosh(\eta)}{\sqrt{s}} \right)$$

$p_{T\min}$ is the minimum transverse momentum cut ($p_T \geq p_{T\min}$)

For fixed $p_{T\min}$ and parameter a , all η dependence through $\cosh(\eta)/\sqrt{s}$

Pseudo-rapidity Plateau in Toy Model

$d\sigma(\eta=0)/d\eta$ vs. \sqrt{s}

Width of plateau controlled by kinematic limit:

$$\eta_{\max} = \ln \left(\frac{\sqrt{s}}{2p_T} + \sqrt{\frac{s}{4p_T^2} - 1} \right)$$

$dN/d\eta$ on plateau $\eta \approx 0$ grows by kinematics – (no QCD required)

$dN/d\eta$ is a function of $\cosh(\eta)/\sqrt{s}$

Toy Model

$$n_{pT} = 6$$

$$n_{xR} = 4$$

$$p_{Tmin} = 10 \text{ GeV}$$

Check of Rapidity Distribution of Jets

13 TeV ATLAS $dN/d\eta$

- Fit: $p_T > 0.1$ TeV with numerical integration of fit function un-normalized.

$$\frac{d^2\sigma}{p_T dp_T d\eta} \sim A(p_T)(1-x_R)^n$$

- Data:

$$\frac{dN}{d\eta} \sim \sum_i \frac{d^2\sigma_i}{p_{Ti} dp_T d\eta} p_{Ti} \Delta p_T$$

Pseudo-rapidity Distribution for Measured Jets

Used the fits of the inclusive jet cross sections: $\{\alpha(\sqrt{s}), n_{pT}(\sqrt{s}), D(\sqrt{s}), n_{0xR}(\sqrt{s})\}$ CDF & ATLAS

Rapidity Plateau (Parameters for $p_T > 100$ GeV)

Rapidity Plateau (Parameters for $p_T > 100$ GeV)

PHOBOS $dN/d\eta$

B.B. Black, et al.
arXiv:nucl-ex/0509034v1 28 Sep 2005
B-field = 0 (very low p_{Tmin})

Region of scaling is high η . Note that $\cosh(\eta)/\sqrt{s}$ scaling similar to η' scaling – see backup.

What about the x_R -Dependence

- Inclusive cross section roughly factorizes: $\sigma \sim A(p_T) (1-x_R)^{n_{xR}}$
 - Would expect that $n_{xR} = n_{xR}(v_s, p_T, \text{process})$ to characterize the fragmentation and hadronization of primordial quark/gluon.
 - Quark line-counting rules suggest $n_{\text{spectator}}$, the number of non-participating quarks in the primary collision, controls the $(1-x_R)$ power:

$$\frac{d^2 \sigma}{p_T dp_T dy} \sim A(p_T) (1 - x_R)^{2n_{\text{spectator}} - 1}$$

Summary of $(1-x_R)^{n_{xR}}$ Power

n_{xR} for Various Processes

Notes:

1. Qualitatively $n_{xR} \approx 2 n_{\text{spectator}} - 1$
2. In cases where n_{xR} is roughly independent of p_T the average values and standard deviations are plotted.
3. In cases where there is a significant $1/p_T$ dependence the value n_{xR0} is plotted, where: $n_{xR}(1/p_T) = D/p_T + n_{xR0}$ and the error of n_{xR0} is shown.
4. Caveat: J/ψ data show inconsistencies among experiments. Trend shown is consistent but details not clear. See backup.

Parton-Parton Elastic Scattering – 2 Examples

Functions of the Mandelstam variables s , t , u and α_s . All have dimensions of $(\text{energy})^{-4}$.

$$\frac{d\hat{\sigma}(\hat{s}, \hat{t}, \hat{u}; ud \rightarrow ud)}{d\hat{t}} = \frac{4\pi\alpha_s^2}{9\hat{t}^2} \frac{\hat{s}^2 + \hat{u}^2}{\hat{s}^2}$$

$$\frac{d\hat{\sigma}(\hat{s}, \hat{t}, \hat{u}; gg \rightarrow gg)}{d\hat{s}} = \frac{9\pi\alpha_s^2}{2\hat{s}^2} \left(3 - \frac{\hat{t}\hat{u}}{\hat{s}^2} - \frac{\hat{s}\hat{u}}{\hat{t}^2} - \frac{\hat{s}\hat{t}}{\hat{u}^2} \right)$$

$$\hat{s} = (p_a + p_b)^2 = \frac{s}{4} (x_1 + x_2)^2$$

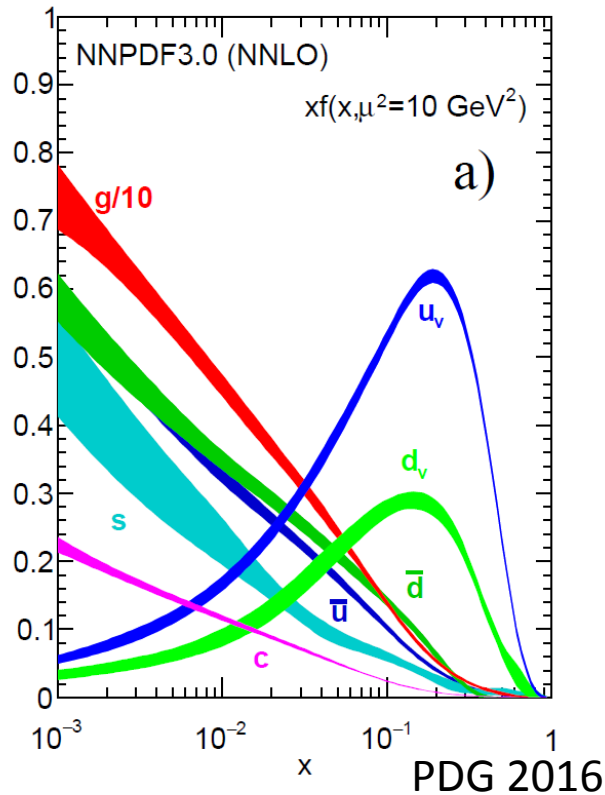

$$\cos\theta = \left(1 - \frac{p_T^2}{\hat{s}} \right)^{1/2}$$

$$\hat{t} = -\frac{\hat{s}}{2} (1 - \cos\theta)$$

$$\hat{u} = -\frac{\hat{s}}{2} (1 + \cos\theta)$$

PDF and DGLAP Evolution and Splitting Functions

Parton Distribution Functions (mostly from DIS Lepton-Nucleon Scattering):

DGLAP evolution and splitting functions:

$$\frac{\partial f_a}{\partial \ln \mu^2} \sim \frac{\alpha_s(\mu^2)}{2\pi} \sum_b (P_{ab} \otimes f_b)$$

$$P_{qg}(x) = \frac{1}{2} [x^2 + (1-x)^2] \dots$$

These 10s of parameters and factors are put together in simulations of inclusive jet production at the LHC.

Integrate over x_R to find p_T Dependence

- J. Thaler suggested:

$$\frac{1}{p_T^{n_{eff}}} \sim \int_{x_{Rmin}}^1 \frac{d^2\sigma}{p_T dp_T dy} \left(\begin{matrix} p_T & y \\ p_T & x_R \end{matrix} \right)_J dx_R$$

$$= \int_{x_{Rmin}}^1 \frac{d^2\sigma}{p_T dp_T dy} \frac{2}{\sqrt{x_R^2 - x_{Rmin}^2}} dx_R$$

$$x_{Rmin} = \frac{2p_T}{\sqrt{s}}$$

n_{pT} increases from 6.0 to 6.45.
Tested with toy model.

pT - Dependence of Integral over xR

Interesting suggestion – integration can be extended to determine the moments of the “fragmentation” function $(1-x_R)^{n_{xR}}$.

Arleo, et al.* – x_T Analysis to Determine n_{p_T}

$$E \frac{d^3\sigma}{dp^3}(ab \rightarrow cX) = \frac{F(x_T, \theta)}{p_T^n}$$

Studied the approach to x_T scaling, evident for small $|y|$ but misses the main feature. Scaling is in x_R not x_T namely $F(x_T, \theta) = F(x_R)$ and the jet cross sections grow with increasing s through the amplitude term $\alpha(s)$.

*[Arleo, Brodsky, Hwang and Sickles; arXiv:0911.4604v2, PRL 105,06200 (2010)]

Replication of the Analysis – Assume x_T Scaling

- Assume $\left\{ \begin{aligned} \sigma^{inv} &\equiv E \frac{d^3 \sigma}{dp^3} (AB \rightarrow CX) = \frac{F(x_T, \theta)}{p_T^n} \\ \sigma^{inv} (AB \rightarrow CX) &\propto \frac{(1 - x_T)^{2n_{spectator} - 1}}{p_T^{2n_{active} - 4}} \\ n^{exp} &= \frac{-\ln \left(\sigma^{inv}(x_T, \sqrt{s_1}) / \sigma^{inv}(x_T, \sqrt{s_2}) \right)}{\ln \left(\sqrt{s_1} / \sqrt{s_2} \right)} \end{aligned} \right.$

Arleo - continued

x_T analysis: power of p_T depends on x_T and process.

h^\pm/π^0 – circles
 γ – squares
 Jets – triangles

n^{exp} determined in a two component model by variation in x_T and p_T for two values of \sqrt{s} .

The x_R analysis finds power of p_T independent of process within errors:
 $n_{p_T} = 6.5 \pm 0.4$

Fig. from Arleo, et al.; arXiv:0911.4604v2, PRL 105,06200 (2010)

n_{eff} without correction term using ATLAS Jet Fits

Find $n_{\text{eff}} \rightarrow 4$ as $x_T \rightarrow 0$

Must formulate the cross sections with this:

$$\sigma^{inv} \equiv E \frac{d^3\sigma}{dp^3}(AB \rightarrow CX) = \frac{\alpha(\sqrt{s})(1-x_R)^{nx_R(\sqrt{s}, pT)}}{p_T^n}$$

• Assume

$$n^{\text{exp}} = \frac{-\ln\left(\sigma^{inv}(x_T, \sqrt{s_1})/\sigma^{inv}(x_T, \sqrt{s_2})\right) + \ln\left(\alpha(\sqrt{s_1})/\alpha(\sqrt{s_2})\right)}{\ln(\sqrt{s_1}/\sqrt{s_2})}$$

n_{eff} with the $\alpha(s)$ cross section amplitude term

Hence $n_{\text{eff}} \rightarrow 4$ as $x_T \rightarrow 0$ is a result of neglecting the ' $\alpha(s)$ ' term that contains important overall normalization that corrects $n_{\text{eff}} \approx 4$ to $n_{\text{eff}} \approx 6$.
